

FERGUSON 501

Four-valve, plus rectifier, three-waveband superhet. Provision is made for a pickup and high resistance loudspeaker. Suitable for operation from AC mains 200-250 v, 50-100 cycles. Marketed by Ferguson Radio Corp. Ltd. Services and spares by TEI Service, 55 Blossom Street, Manchester 4.

AERIAL signals are fed via C1 and C2 to the short wave coupling coil L2. Coupling on medium and long waves is effected by C3 to the grid coils L4 (MW), L5 (LW). L1 is claimed to minimise modulation hum with R1 to broaden any resonant peak.

Signals from the grid coils are fed to the control grid of the frequency-changer V1, which is cathode biased by R3, decoupled by C5. The oscillator section employs tuned grid circuits L6 (SW), L8 (MW) and L10 (LW). Feed-back is established by L7 and L9 on SW and MW with common coupling across T13 on LW.

An intermediate frequency transformer L11, L12 couples V1 to the IF amplifier pentode V2, which is biased by R10 decoupled by C11. A second IF

transformer L13, L14 passes on the signal to the strapped diodes of the double diode triode V3.

The load resistance is R11, and LF signals are fed via C12 to the volume control VR1. The DC component across R11 is used for automatic volume control and is applied via decoupling components to the grid circuits of V1 and V2.

V3 is cathode biased by R12, decoupled by C16, and a variable tone control comprising VR2, C14 and C15 is connected across the signal load circuit. Pickup sockets are provided across the volume control input.

VALVE READINGS

condensers C21, C22. Mains HF filtering is provided by C23.

GANGING

IF Circuits.—Switch receiver to long waves and tune condenser to maximum capacity.

Inject a 465 kc signal into the grid cap. of V2, and adjust T1, T2, T3, and T4 for maximum output, keeping the input low to avoid AVC action.

These two diagrams identify the components above and below the Ferguson chassis.

Below, details of the single switch bank. On the left is the view as seen from the back of the chassis.

SW Band.—Check tuning pointer. It should be vertical when the gang is at maximum capacity. Marks on the scale are provided for this check.

First adjust T7, T10 and T13 at the upper end of each band with the gang condenser at maximum capacity. This may be accomplished by connecting a high frequency signal via a 50 mmfd condenser to aerial lead and adjusting the trackers for maximum output.

Switch receiver to SW and inject a 21 m signal into the aerial and earth leads. Tune receiver to 21 m on scale and adjust T5, T6 for maximum output.

Adjust tuning condenser to full capacity and re-adjust T7 as described above. Check adjustments of T5 and T6. If T5 peaks at two places, adjust to the peak with the least trimmer capacity.

MW Band.—Inject a signal of 250 m. Tune receiver to this wavelength on the scale, and adjust

T8 and T9 for maximum output. Adjust tracking condenser T10 as described above.
LW Band.—Switch receiver to LW. Tune it to 1200 m. and inject a signal of this wavelength. Adjust T11 and T12 for maximum output, and track T13 as described above.

Technical Reasons Why

★ ERSIN MULTICORE SOLDER

Is the Finest Cored Solder in the World

3 CORES OF FLUX

Three Cores of Flux ensure flux continuity. No lengths without flux are wasted. Consistent high quality joints are obtained with comparatively unskilled labour. Exactly the correct proportions of solder to flux are provided. Separate fluxing operations are obviated and no extra flux is required. The three cores of flux being evenly distributed over the cross section of the solder provide thinner solder walls than otherwise. This gives rapid melting and speeds up soldering. The flux does not tend to run out of the cores, so there is always a supply available for the next joint. The utmost economy of solder and flux is achieved.

Ersin, contained in the three cores of Ersin Multicore Solder, is the fastest non-corrosive flux. Possessing all the non-corrosive advantages of rosin, it enables joints to be speedily made on oxidised or "difficult" surfaces such as nickel. Ersin not only avoids oxidation during soldering but removes surface oxide already present—this is particularly advantageous in respect of materials that have been in stock or apparatus that is being serviced. The use of Ersin Multicore, with correct soldering technique, avoids "HR" or dry joints.

10 SWG
22 SWG
Double actual size.

Ersin Multicore Solder is made in most gauges between 10 and 22 S.W.G. (.128—-.028") (3.251—7109 m/ms). For general radio and electrical production and maintenance 13 and 16 S.W.G. are in most demand.

Five alloys of Ersin Multicore Solder are available—all antimony free. Under present circumstances 45% tin and 55% lead is the most widely used alloy.

Virgin
Tin & Lead

Technically, Ersin Multicore Solder is far superior to any other cored solder. A practical laboratory or production test will demonstrate this and show you that it is the most economical solder to use. The majority of British and overseas manufacturers already enjoy the advantages of Multicore. If you do not, and are engaged upon Government contracts, write for further technical information and free samples.
